

Assessment

Module-13:React js (AddToCart App) – Applying Redux

Case Overview

Scenario:

You are tasked with building a scalable React + Redux application to manage customer complaints. The system must integrate with a REST API using Redux Toolkit, allow form submissions, manage records with search and filter features, and support create, update, and delete operations.

Core Functionality

Feature	Description
Responsive AddProducts Web Form	Fields: ProductName - text,Price - number,Offerprice - number,Photo - blob,Qty -number ,Descriptions -text ,added_date - (datae formate)
Data Submission	Use createSlice for crud. On valid submission, send POST request to API. Update Redux store and UI instantly.
View Submission	Fetch data from api and display in table with columns:Name,Phone,Email,Address.Include search filter by Name.Show “No records found” if empty.
Delete Record	Add Delete button for each <u>record</u>. On click,confirm action, send DELETE request to api, remove from UI immediately.
Edit Record	Add edit button for each record.Put request use for update.

Key Competencies Tested

- React Form Handling & Controlled Components
- JavaScript Input Validation
- Redux Toolkit (createSlice, createAsyncThunk, useDispatch, useSelector)
- API Integration (GET, POST, PUT, DELETE)
- Search & Filter Logic
- Real-time UI Updates via Redux Store
- Context API for UI state
- RTK Query for advanced API handling

Reflective Thinking Questions

- How would Redux or Context API improve state management in this app?
- Could RTK Query make API integration more efficient?
- What authentication method would you implement to secure CRUD operations?
